

Second Substitute Specification 09/827,462

METHOD FOR PRODUCING CUTTING TOOLS

CROSS-REFERENCE TO RELATED APPLICATION

This is a divisional of application number 09/253,212 filed February 19, 1999 and now U.S. Patent 6,241,431, which claimed priority from European Patent application number 99 103093.3 file February 17, 1999.

FIELD AND BACKGROUND OF THE INVENTION

Definitions

In the present specification ~~by~~hard material ~~is~~understoodmeans a compound, namely a carbide, oxide, oxycarbide, but in particular a nitride, nitrocarbide, oxynitride or nitrooxycarbide, of at least two of the metallic elements listed in the following, in particular of Ti and Al. ~~By~~Metallic elements ~~are~~understoodmeans Ti, Zr, Hf, V, Nb, Ta, Cr, Mo, W and Al.—

If within the scope of the present application reference is made to a change of the composition of the hard material layer material in the active edge region, ~~by~~that ~~is~~understoodthis means a difference of at least 2 at% of a hard material layer

metal component between a hard material layer in the active edge region and a hard material layer in the remaining regions of the tool.

Analogously, no change exists if the stated difference is less than 2 at%, in particular less than 1 at%.

~~By~~ <sup>m</sup>Machining cross section  $f a_p$  ~~is understood~~ means the product "Vorschub x Schnitttiefe" {Advance x cutting depth} according to DIN 6580, Section 11.1.1, "Bewegungen und Geometrie des Zerspanungsvorgang" [Motions and Geometry of the Machining Process] (DN 6580, Oct. 1985).

German Patent DE 38 25 399 as well as European Patent EP 0 352 545 disclose coating tools by means of a vacuum process with a layer of hard material, and therein especially with a (Ti,Al)N hard material layer. The coating takes place such that in the active edge region, i.e. in the region of the cutting edges, the hard material layer material has a changed composition compared with that on the remaining tool regions: according to DE 38 25 399 as well as EP 0 352 545 at the active edge regions of drills a thinning out of the aluminum is realized which is distinguishable on the tools by the reddish or yellowish coloration of these regions. Thinning-out ratios of 5 at% or 2 percent by mass of the Al are declared.

#### SUMMARY OF THE INVENTION

The process discovered, namely to change the hard material layer composition in the active edge region, is fundamentally represented as a measure for attaining a significant improvement

of the quality of the coating.

~~Building~~ The invention starts from the understanding that generally ~~on~~, tools in ~~which the provided~~ have a hard material layer in their active edge region ~~has~~ which is substantially, and within the scope of measurability, an unchanged material composition ~~as well as on tools in which, i.~~ In contrast ~~to the first stated~~, the composition of the hard material layer in the active edge region is changed, ~~each~~ relative to the hard material layer composition on the remaining tool regions, ~~it is the task of~~ according to the present invention ~~to~~. The invention proposes a process for the protective coating of machining tools as well as a set of at least two tools, by means of which substantially improved specific working properties are attained. In particular, ~~as a working property to be improved is understood~~ properties such as the service life of the tool or the decrease of the tool wear, are improved.

According to the process of the invention, ~~onto the basic tool body~~ a hard material layer is applied ~~in any case but, specific to the tool stress, the~~ onto the basic tool body but is selected for the specific stress the tool is meant to endure. The composition of the hard material layer in the active edge region is either left with minimum changes relative to the composition of the hard material layer in the remaining coating regions on the tool basic body or is intentionally changed. The former, *i.e.* constant composition, is realized if the primary requirements to be made of the tools relate to adhesive strength of the hard material layer and only secondarily to hardness of the hard material layer. The second, in contrast, is realized if

the primary requirements to be made of the tools relate to hardness of the hard material layer and only secondarily to adhesive strength of the hard material layer.

According to the invention it was ~~consequently found that the estimating, previously described effective specifications of changed or unchanged~~ found that by changing or not changing the compositions of the hard material layers in the active edge regions of machining tools are not ~~permissible, that namely, as a function of the working purpose of the tools, one time~~ that is, by either providing a hard material coating of constant composition ~~and another time~~ or a hard material coating of varying composition in the active edge region in practice, ~~i.e. when applying the tool, only leads to critical improvements~~ were realized. If tools for given ~~application conditions~~ applications, are coated with the wrong coating ~~technologies one~~ technique of the two mentioned, ~~therewith often an impairment of its~~ the tools' working properties, in particular tool life, ~~is obtained results.~~ -

It could be shown, for example, that according to EP 0 352 545 with a thinning-out of the coating only in a few ~~application fields of machining~~ working, better or at least equally good results can be achieved, compared to the application of corresponding tools with a lower or no, at least not measurable, difference in the concentration of the hard material layer. It should be pointed out, in particular, that the example mentioned in EP 0 352 545 with respect to service life of twist drills, based on the representative comparisons made according to the present invention, is erroneous in the case where two completely identical, except for stated coating difference, and identically

coated drills are present. By the phrase completely identical is  
~~therein understood the~~ here means an application of the same  
coating processes, in particular arc or sputtering processes, on  
identical tool bodies, and the adjustment of the realized or  
~~nonrealized~~ not realized concentration difference ~~takes place~~  
exclusively by adjusting the voltage applied on the basic tool  
body during the coating with respect to ground or reference  
potential, referred to as bias voltage  $U_{bias}$  in the following,  
and/or of the reactive gas partial pressure  $p_{reactiv}$  in the vacuum  
coating receptacle with further process parameters remaining  
unchanged.—

¶It can be seen that the prior known thinning-out in the  
active edge region can effect critical disadvantages in the use  
of the tool, and that consequently it is necessary to assess very  
carefully according to the invention, which process is applied at  
which time, ~~can be seen~~, for example, by the fact that precisely  
the aluminum depletion of the hard material layer in the active  
edge region has negative effects on ~~the~~ wear through thermal  
stress of the hard material layer since through the aluminum  
thinning-out potentially, now less aluminum reaches the surface  
of the hard material layer through diffusion and no continuous  
thermally insulating aluminum oxide layer can be formed there.  
The  $Al_2O_3$  layer on the surface is simultaneously worn out during  
the working process and formed again through Al diffusion. But  
precisely this phenomenon can critically influence the durability  
of ~~a provided~~ the hard material layer with aluminum component  
under specific conditions of application.

According to the invention as explained in the following

examples, it could be shown that tools with a hard material layer, in particular a (Ti,Al)N layer, comprising ~~at least~~ only a low or no longer measurable composition change of the material of the hard material layer in the active edge region, in many ~~application cases~~ applications yield a substantially better service life, even with increased cutting efficiency, than other tools, that are otherwise identical, with a composition change of the hard material layer in the active edge region. Especially good results can be achieved, in the case given first, if, in the active edge region, the change of one of the metal components of the hard material layer is less than 2 at%, preferably it is maximally 1 at% or no longer measurable.-

Following another feature of the invention, when using arc vaporization for depositing the hard material layer, an as much as possible unchanged hard material layer composition in the active edge region is attained ~~thereby that for~~ when the ratio  $U_{BIAS}$  - of the electric basic tool body voltage relative to reference potential, usually ground potential, - to the partial pressure of the reactive gas  $p_{reactiv}$ , has the following range ~~is maintained~~ of values:

$$1 \times 10^{-3} \leq U_{BIAS}/p_{reactiv} \leq 4 \times 10^3,$$

with the unit of voltage being "volt" and the unit of pressure "mbar".

Furthermore the invention produces drills, roughing milling cutters, peripheral milling cutters and hobbing machines with as much as possible unchanged composition of the hard material layer in the active edge region, ~~however~~ and front-end milling cutters and ball-end milling cutters with changed composition of the hard

material layer in the active edge region.

It was in particular found that the composition of the hard material layer in the active edge region of the tools should be ~~realized~~unchanged, as ~~much~~far as possible ~~unchanged~~, if these tools are intended for the working of relatively large voltage or cross sections and for low cutting rates; however, ~~that~~tools should be prepared with a changed composition of the hard material layer in the active edge region if the ~~latter~~tools are intended for relatively low voltage machining cross sections but relatively high cutting rates.

A further criterion for making the selection according to the invention, of the type of hard material coating in the active edge region of the tools ~~results thereby that~~, is for the working of materials with a hardness of at most 45 Rockwell (HRS) and a tensile strength up to at most 1500 N/mm<sup>2</sup>, preferred for the working of heat-treatable steels, high-alloy and stainless steels as well as of nonferrous metals, to carry out the coating with hard material in the active edge region as much as possible without changing the composition. The same applies to tools whose active edges in ~~application~~use are simultaneously subjected to different cutting rates, such as in particular ~~to~~, drills on which a minimum cutting rate occurs at the tip of the drill and a high rate on the drill periphery.

Basic tool bodies are coated in the active edge region with changed composition of the hard material layer, which are intended for the machining working of materials with a hardness of more than 45 Rockwell (HRC) and with a tensile strength of

more than 1500 N/mm<sup>2</sup>, in particular for operations involving the removal of hard metal by cutting tools, for example, instead of grinding or erosion processes.—

In the following AISI refers to known materials categorized by the American Iron and Steel Institute and DIN refers to materials categorized by the Deutsches Institut für Normung (German Standards Institute). Other known standards are also used to identify other material types.

It has in particular been found, that

- indexable inserts for turning tools and for materials AISI 304SS or DIN 1.4306 to be worked,
- indexable inserts for peripheral milling cutters for materials AISI 4140 or —DIN 1.7225 to be worked,
- indexable inserts SEE 42TN for milling cutters for material SKD 61 (HRC 45) to be worked,
- hard metal roughing shank-type milling cutters for materials DIN 1.2344 to be worked in dry working, as well as
- HSS drills for materials AISI D3 or DIN 1.2080 as well as GG 25 to be worked with emulsion lubrication

should be realized as much as possible with unchanged composition of the hard material layer in the active edge region;

however

- hard metal roughing shank-type milling cutters for materials DIN 1.2311 to be worked with emulsion lubrication
- hard metal front-end milling cutters for materials AISI D2 or DIN 1.237 to be worked
- hard metal ball-end milling cutters J97 for dry working of DIN 1.2343, 49.5 HRC, preferably with changed composition of the hard material layer in the active edge region.

Further, at least two tools are therein provided, one for a first specific application operation in which primarily high adhesion strength of the hard material layer is required, however, only secondarily high hardness of the hard material layer, and a second tool, during the application of which primarily high hardness of the hard material layer is required and only secondarily high adhesion strength of this layer.

In this tool set according to the invention, the first tool is coated in the active edge region with substantially uniform composition of the hard material layer, however the second one with varying composition of the hard material layer.

Whether or not a tool is provided with a hard material coating whose composition in the active edge region is changed, is often evident by the coating coloration of the tool in the

active edge region, thus typically for (Ti,Al)N layers with Al depletion in the active edge region through its yellowish or reddish coloration in stated region.-

Through the present specification and the claims, the relevant expert gains clear instructions, based on which criteria he is to investigate, which active edge hard material coating techniques lead to better tool application behavior. Even when in specification and claims specific tool types as well as their type of application and the materials to be worked are specified, this is not to be understood to be conclusive for the expert but rather he recognizes, based on the evaluation of the useful coating type for further tools for further application fields and materials, considered by analogy, which coating technique is to be applied, or he obtains the advice first of all to try which of the two coating techniques leads to better results.

#### **BRIEF DESCRIPTION OF THE DRAWINGS**

In the following the invention will be explained with reference to examples and, in connection therewith, to Figures.—  
~~Therein depict~~ the drawing, wherein:

Fig. 1 is an Auger line scan diagram, recorded in the active edge region, by example of an indexable insert of type SNGA 120408, at right angles to the active edge.—, the titanium and aluminum distribution ~~is~~ being recognizably uniform, corresponding to an unchanged composition of the hard material layer in the active edge region,;

Fig. 2 is an Auger line scan diagram recorded on the same object as in Figure 1, however, on which the titanium and aluminum distribution in the active edge region is of changed composition of the material of the hard material layer; and

Fig. 3 is a simplified and schematically, diagram of a view onto an installation used for the described experiments.

#### DESCRIPTION OF THE PREFERRED EMBODIMENTS

In the discussed examples, identical basic tool bodies were in each instance coated by means of arc vaporization. In examples 1 to 4 the coating conditions specified in the following by A and B were selected. The layer thickness, in particular in the active edge region, was approximately 3.5  $\mu\text{m}$ .

The coatings realized under A show a uniform titanium or aluminum distribution according to the Auger line scan of Figure 1. It was recorded starting on the edge of an indexable insert of Type SNGA 120408 coated according to A at right angles to the active edge or the polished machining face to a length of 0.5 mm, corresponding to approximately 60 measuring points per scan. The hardness of the layers realized under A was approximately 3000 HV<sub>0.05</sub>.

The parameters described under B yield layers which in the active edge region (that is on either side of the edge proper) and have a strong depletion of the aluminum, namely from 50 at% (on the edge) to 40 at%, or an enrichment of titanium from 50 at%

(on the edge) to 60 at%, according to Figure 2. With more sharply pronounced edges, such as for example in the case of knife cutters, markedly greater differences in the material composition of the hard layer could be measured. The hardness of the layers deposited under B is approximately  $3500 \text{ HV}_{0.05}$ . In the following tables, the two parameter sets A and B for the arc vaporization coating are summarized.

All experiments were carried out on an installation BAJ 1200 under production conditions.

In Figure 3 the view onto an installation of the given type is shown schematically. In a cylindrical treatment chamber 1 a revolving table is supported rotatably with respect to the central axis  $A_1$  as shown with the rotational motion  $\omega_1$ . On the revolving table several substrate carrier arrangements 3 are supported each rotatable about axes  $A_2$ , as is shown with the rotational motion  $\omega_2$ . On the substrate carrier arrangements 3 are supported in individual substrate carriers the substrates 5 grouped about the particular axis  $A_2$ , which substrates are preferably themselves, and as shown with  $\omega_3$  driven about their own axis, set into rotational motion.

Onto the wall of the chamber 1 are flanged one or several arc vaporizer sources 7. With respect to the specific and detailed structure of the installation used, reference is made for example to US A 5 709 784 by the same applicant.-

In the experiments exclusively  $\text{N}_2$  gas was used, i.e. as the working gas as well as also the reactive gas. It is understood

that additionally also an inert gas, in particular argon, can be used as the working gas. For the coating of type A the total pressure, i.e. the  $N_2$  pressure, was approximately  $3 \times 10^{-2}$  mbars, for the experiments B approximately  $1 \times 10^{-2}$  mbars.

Ti, Al was arc-vaporized from alloy targets.

In the following tables denote further:

$P_{N_2}$  : partial pressure of reactive gas  $N_2$

$I_{Ti}$  : arc current during titanium vaporization

$I_{TiAl}$  : arc current during TiAl alloy vaporization

Coating Parameters A:

Parameter	TiN Intermediate Layer	(TiAl)N Hard Material Layer
$P_{N_2}$ [mbar]	$8 \times 10^{-3}$	$3.2 \times 10^{-2}$
$I_{Ti}$ [A]	170	0
$I_{TiAl}$ [A]	0	200
$U_{BIAS}$ [V]	-200	-40

Coating Parameters B:

Parameter	TiN Intermediate Layer	(TiAl)N Hard Material Layer
$P_{N_2}$ [mbar]	$8 \times 10^{-1}$	$1 \times 10^{-1}$
$I_{Ti}$ [A]	170	0

$I_{TIA}$	[A]	0	200
$U_{BIAS}$	[V]	-150	-150

In all cases a TiN intermediate layer was installed between basic tool body and hard material layer.

Example 1

Tool : Turning tools with indexable insert K313/CNGP432

Material worked : AISI 304SS  $\approx$  DIN 1.4306

Cutting rate :  $v_c = 244$  m/min

Advance per rotation :  $f_u = 0.2$  mm/r

Cutting depth :  $a_p = 1.524$  mm

Lubricant : emulsion

Experiment No.	Layer	Working Cycles	Cycle Average
1	TiN	7.5	6.8
2		6.5	
3		6.5	
4	TiAlN "A"	21.0	18.3
5		17.0	
6		17.0	
7	TiAlN "B"	6.4	5.8
8		5.5	
9		5.5	

Example 2

Tool : Peripheral milling cutters with indexable insert K903/SEHW43A6T

Material worked : AISI 4140  $\approx$  DIN 1.7225

Cutting rate :  $v_c = 1152$  m/min

Advance per rotation :  $f_t = 0.25$  mm/r

Cutting depth :  $a_p = 2.54$  mm

Lubricant : emulsion

Experiment No.	Layer	Working Cycles	Cycle Average
10	TiN	15.0	14.8
11		13.0	
12		15.5	
13		15.5	
14	TiAlN "A"	37.0	24.8
15		19.0	
16		21.5	
17		21.5	
18	TiAlN "B"	13.0	12
19		11.0	
20		12.0	
21		12.0	

### Example 3

Tool : HSS drill, 6 mm

Material worked : AISI D3  $\approx$  DIN 1.2080

Cutting rate :  $v_c = 35$  m/min

Advance per rotation :  $f_u = 0.12$  mm/r

Engagement size :  $a_e = 3$  mm

Drilling depth :  $h = 15$  mm, pocket hole

Lubricant : 5% emulsion

Experiment No.	Layer	Average Number of Holes

hard material is worked dry. The tools coated with the parameters A and consequently tools with unchanged composition of the hard material layers in the active edge region show markedly lower wear mark widths than tools with changed composition of the hard material layer in the active edge region.

Example 4b

Tool : Hard metal roughing shank-type milling cutter,  
 $\phi = 10 \text{ mm}$ , 25/64

Teeth number :  $z = 3$

Machined material : DIN 1.2311, 33 HRC,  $R_m = 1050 \text{ N/mm}^2$

Cutting rate :  $v_c = 100 \text{ m/min}$

Advance per rotation :  $f_t = 0.035 \text{ mm/tooth}$

Engagement size :  $a_e = 3 \text{ mm}$  -

Cutting depth :  $a_p = 16 \text{ mm}$  -

Lubricant : 5 % emulsion

Experiment No.	Layer	Average Length of Path
24	TiN	24
25	TiCN	27
26	TiAlN "A"	42
27	TiAlN "B"	78

This example makes evident that at high cutting rate and additional emulsion lubrication, further with relatively soft material to be worked, on average greater path lengths are achieved with the coating technique according to B.

Consequently, Examples 4a and 4b show that in similar operations but different conditions of use, identical tools coated differently in the active edge region are advantageous in each instance.

In the following Examples 5 to 9 further tools are specified with the particular applicable coating parameters analogous to A and B. Those tools with constant composition of the hard material layer in the active edge region are denoted by  $A_0$ , analogous tools with changed composition of the hard material layer in the active edge region by  $B_0$ . Apart from the specified coating parameters, identical basic tool bodies were coated with identical coating processes and compared with one another with respect to their service life.

#### Example 5

Tool : milling cutter with indexable inserts SEE 42 TN (G9)  
Teeth number :  $z = 6$   
Layer thickness  $(Ti_xAl_y)N$  : each  $4.5 \mu m$   
Material worked : SKD 61 (HRC45)  
Cutting rate :  $v_c = 100 m/min$   
Advance per tooth :  $f_z = 0.1 mm/tooth$   
Cutting depth :  $a_p = 2 mm$

Samples	No.	Coating Conditions			Al decrease toward edge [at%]	Cutting length [m]
		Bias [-V]	N2 [ $10^{-2}$ mbars]	Arc Current [A]		

A <sub>c</sub>	32	60	2.5	150	1	3.2
	33	60	3.2	150	1	3.0
	34	40	2.0	150	0	8.8
	35	40	4.0	150	0	3.9
	36	40	0.5	150	0	2.0
	37	30	2.0	150	0	4.2

	40	150	2.0	150	4	0.5

### Example 6

Tool : HSS drill,  $\varnothing$  6 mm

Layer thickness  $(Ti_xAl_y)N$  : each 5  $\mu m$

Intermediate TiN layer : each 0.5  $\mu m$

Material worked

(with emulsion) : DIN 1.2080 (AISI D3)

Cutting rate :  $v_c = 40$  m/min

Advance :  $f = 0.10$  mm/r

Drilling depth : 15 mm (pocket hole)

Samples	No.	Coating Conditions			Al decrease toward edge [at%]	Number boreholes
		Bias [-V]	N2 [10 <sup>-2</sup> mbars]	Arc Current [A]		
A <sub>c</sub>	41	40	3.0	200	0	198
	42	40	3.0	200	0	231
B <sub>c</sub>	43	150	1.0	200	7	45
	44	150	1.0	200	7	38

### Example 7

Tool : HSS roughing milling cutter,  $\varnothing$  12 mm

Number of teeth :  $z = 4$   
 Layer thickness  $(Ti_xAl_y)N$  : each  $4.5 \mu m$   
 Intermediate TiN layer : each  $0.3 \mu m$   
 Material worked dry : DIN 1.2344 (AISI H13)  
 Cutting rate :  $v_c = 120 \text{ m/min}$   
 Advance per tooth :  $f_z = 0.6 \text{ mm/tooth}$   
 Cutting depth :  $a_p = 20 \text{ mm}$   
 Engagement size :  $a_e = 5 \text{ mm}$

Samples	No.	Coating Conditions			Al decrease toward edge [at%]	Cutting length [m]
		Bias [-V]	N2 [ $10^{-2}$ mbars]	Arc Current [A]		
A <sub>0</sub>	45	40	2.5	200	0	41
B <sub>0</sub>	46	150	1.0	200	7	12

#### Example 8

Tool : Hard metal drill,  $\phi 11.8 \text{ mm}$   
 Layer thickness  $(Ti_xAl_y)N$  : each  $5 \mu m$   
 Intermediate TiN layer : each  $0.5 \mu m$   
 Material worked  
(with emulsion) : GG 25 (gray cast iron)  
 Cutting rate :  $v_c = 110 \text{ m/min}$   
 Advance :  $f = 0.4 \text{ mm/r}$   
 Drilling depth : 35 mm (pocket hole)

Samples	No.	Coating Conditions			Al decrease toward edge [at%]	Number borehole s
		Bias [-V]	N2 [10 <sup>-2</sup> mbars]	Arc Current [A]		
A	47	40	3.0	200	0	2840
B <sub>6</sub>	48	150	1.1	200	7	1270

Example 9

Tool : Hard metal indexable insert, external turning  
Layer thickness  $(Ti_xAl_y)N$  : each 5  $\mu m$   
Intermediate TiN layer : each 0.2  $\mu m$   
Material worked  
(with lubrication) : DIN 1.4306 (X2CrNi 1911)  
Cutting rate :  $v_c = 240$  m/min  
Advance per rotation:  $f = 0.6$  mm  
Cutting depth :  $a_p = 1.5$  mm

<b>Samples</b>	<b>No.</b>	<b>Coating Conditions</b>			<b>Al decrease toward edge [at%]</b>	<b>Cutting length [m]</b>
		Bias [-V]	N2 [ $10^{-2}$ mbars]	Arc Current [A]		
A <sub>6</sub>	49	40	3.0	200	0	4.732
B <sub>6</sub>	50	150	1.0	200	7	2.015

The Examples 5 to 9 show the superiority of tools with unchanged hard material layer composition in the active edge region in different specific applications.

Example 10

Tool : Hard metal front-end milling cutter,  $\phi$  10 mm  
Tooth number :  $z = 6$   
Layer thickness  $(Ti_xAl_y)N$  : each 3.5  $\mu m$   
Material worked dry AISI (DIN 1.2379), 60 HRC  
Cutting rate :  $v_c = 20$  m/min  
Advance per tooth :  $f_z = 0.035$  mm/tooth  
Cutting depth :  $a_p = 15$  mm  
Engagement size :  $a_e = 1$  mm

<b>Samples</b>	<b>No.</b>	<b>Coating Conditions</b>			<b>Al decrease toward edge [at%]</b>	<b>Cutting length [m]</b>

Example 12

Tool : Hard metal ball-end milling cutter J97  
(Jabro), R4 ( $\varnothing 8 \times 65 \text{ mm}$ )

Layer thickness  $(\text{Ti}_x\text{Al}_y)\text{N}$  : each  $3.5 \mu\text{m}$

Intermediate TiN layer : each  $0.1 \mu\text{m}$

Material worked dry : DIN 1.2343, 49.5 HRC

Cutting rate :  $v_c = 240 \text{ m/min}$

Cutting depth :  $a_p = 0.5 \text{ mm}$

<b>Samples</b>	<b>No.</b>	<b>Coating Conditions</b>			<b>Al decrease toward edge [at%]</b>	<b>Cutting length [m]</b>
		<b>Bias [-V]</b>	<b>N2 [10<sup>-2</sup> mbars]</b>	<b>Arc Current [A]</b>		
A <sub>0</sub>	57	40	3.0	200	0	111
B <sub>0</sub>	58	150	1.0	200	7	168

Examples 10 to 12 show that under certain application conditions and with specific tools the service lives are increased if the composition of the hard metal layer is changed in the active edge region.
